B.6 Problems

Hexadecimal notation is used not only for representing integers. It is also used as a concise notation for representing any sequence of binary digits, whether they represent text, numbers, or some other type of data. The reasons for using hexadecimal notation are as follows:

1. It is more compact than binary notation.
2. In most computers, binary data occupy some multiple of 4 bits, and hence some multiple of a single hexadecimal digit.
3. It is extremely easy to convert between binary and hexadecimal.

As an example of the last point, consider the binary string 110111100001. This is equivalent to

$$\begin{array}{ccccccc} 1101 & 1110 & 0001 & = & DE1_{16} \\ D & E & 1 & & \end{array}$$

This process is performed so naturally that an experienced programmer can mentally convert visual representations of binary data to their hexadecimal equivalent without written effort

A.5 PROBLEMS

- A.1** Convert the following binary numbers to their decimal equivalents:
 a. 001100 b. 000011 c. 011100 d. 111100 e. 101010
- A.2** Convert the following binary numbers to their decimal equivalents:
 a. 11100.011 b. 110011.10011 c. 1010101010.1
- A.3** Convert the following decimal numbers to their binary equivalents:
 a. 64 b. 100 c. 111 d. 145 e. 255
- A.4** Convert the following decimal numbers to their binary equivalents:
 a. 34.75 b. 25.25 c. 27.1875
- A.5** Express the following octal numbers in hexadecimal notation:
 a. 12 b. 5655 c. 2550276 d. 76545336 e. 3726755
- A.6** Convert the following hexadecimal numbers to their decimal equivalents:
 a. C b. 9F c. D52 d. 67E e. ABCD
- A.7** Convert the following hexadecimal numbers to their decimal equivalents:
 a. F.4 b. D3.E c. 1111.1 d. 888.8 e. EBA.C
- A.8** Convert the following decimal numbers to their hexadecimal equivalents:
 a. 16 b. 80 c. 2560 d. 3000 e. 62,500
- A.9** Convert the following decimal numbers to their hexadecimal equivalents:
 a. 204.125 b. 255.875 c. 631.25 d. 10000.00390625
- A.10** Convert the following hexadecimal numbers to their binary equivalents:
 a. E b. 1C c. A64 d. 1FC e. 239.4
- A.11** Convert the following binary numbers to their hexadecimal equivalents:
 a. 1001.1111 b. 110101.011001 c. 10100111.111011
- A.12** Prove that every real number with a terminating binary representation (finite number of digits to the right of the binary point) also has a terminating decimal representation (finite number of digits to the right of the decimal point).

(a) $0.81_{10} = 0.11011_2$ (approximately)(b) $0.25_{10} = 0.01_2$ (exactly)**Figure A.2** Examples of Converting from Decimal Notation to Binary Notation for Fractions

Instead, a notation known as hexadecimal has been adopted. Binary digits are grouped into sets of four. Each possible combination of four binary digits is given a symbol, as follows:

0000 = 0	0100 = 4	1000 = 8	1100 = C
0001 = 1	0101 = 5	1001 = 9	1101 = D
0010 = 2	0110 = 6	1010 = A	1110 = E
		1011 = B	1111 = F

Because 16 symbols are used, the notation is called **hexadecimal**, and the 16 symbols are the **hexadecimal digits**.

A sequence of hexadecimal digits can be thought of as representing an integer in base 16. Thus,

$$\begin{aligned} 2C_{16} &= (2_{16} \times 16^1) + (C_{16} \times 16^0) \\ &= (2_{10} \times 16^1) + (12_{10} \times 16^0) = 44 \end{aligned}$$

Fractions

For the fractional part, recall that in binary notation, a number with a value between 0 and 1 is represented by

$$0.b_{-1}b_{-2}b_{-3}\dots \quad b_i = 0 \text{ or } 1$$

and has the value

$$(b_{-1} \times 2^{-1}) + (b_{-2} \times 2^{-2}) + (b_{-3} \times 2^{-3}) \dots$$

This can be rewritten as

$$2^{-1} \times (b_{-1} + 2^{-1} \times (b_{-2} + 2^{-1} \times (b_{-3} + \dots$$

This expression suggests a technique for conversion. Suppose we want to convert the number F ($0 < F < 1$) from decimal to binary notation. We know that F can be expressed in the form

$$F = 2^{-1} \times (b_{-1} + 2^{-1} \times (b_{-2} + 2^{-1} \times (b_{-3} + \dots$$

If we multiply F by 2, we obtain

$$2 \times F = b_{-1} + 2^{-1} \times (b_{-2} + 2^{-1} \times (b_{-3} + \dots$$

From this equation, we see that the integer part of $(2 \times F)$, which must be either 0 or 1 because $0 < F < 1$, is simply b_{-1} . So we can say $(2 \times F) = b_{-1} + F_1$, where $0 < F_1 < 1$ and where

$$F_1 = 2^{-1} \times (b_{-2} + 2^{-1} \times (b_{-3} + 2^{-1} \times (b_{-4} + \dots$$

To find b_{-2} , we repeat the process. Therefore, the conversion algorithm involves repeated multiplication by 2. At each step, the fractional part of the number from the previous step is multiplied by 2. The digit to the left of the decimal point in the product will be 0 or 1 and contributes to the binary representation, starting with the most significant digit. The fractional part of the product is used as the multiplicand in the next step. Figure A.2 shows two examples.

This process is not necessarily exact; that is, a decimal fraction with a finite number of digits may require a binary fraction with an infinite number of digits. In such cases, the conversion algorithm is usually halted after a prespecified number of steps, depending on the desired accuracy.

A.4 HEXADECIMAL NOTATION

Because of the inherent binary nature of digital computer components, all forms of data within computers are represented by various binary codes. However, no matter how convenient the binary system is for computers, it is exceedingly cumbersome for human beings. Consequently, most computer professionals who must spend time working with the actual raw data in the computer prefer a more compact notation.

What notation to use? One possibility is the decimal notation. This is certainly more compact than binary notation, but it is awkward because of the tediousness of converting between base 2 and base 10.

we have

$$N = (N_3 \times 2^3) + (R_2 \times 2^2) + (R_1 \times 2^1) + R_0$$

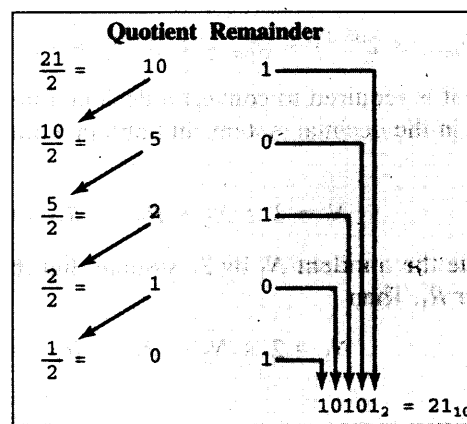

Because $N > N_1 > N_2 \dots$, continuing this sequence will eventually produce a quotient $N_{m-1} = 1$ (except for the decimal integers 0 and 1, whose binary equivalents are 0 and 1, respectively) and a remainder R_{m-2} , which is 0 or 1. Then

$$N = (1 \times 2^{m-1}) + (R_{m-2} \times 2^{m-2}) + \dots + (R_2 \times 2^2) + (R_1 \times 2^1) + R_0$$

which is the binary form of N . Hence, we convert from base 10 to base 2 by repeated divisions by 2. The remainders and the final quotient, 1, give us, in order of increasing significance, the binary digits of N . Figure A.1 shows two examples.

(a) 11_{10}

(b) 21_{10}

Figure A.1 Examples of Converting from Decimal Notation to Binary Notation for Integers

To represent larger numbers, as with decimal notation, each digit in a binary number has a value depending on its position:

$$10_2 = (1 \times 2^1) + (0 \times 2^0) = 2_{10}$$

$$11_2 = (1 \times 2^1) + (1 \times 2^0) = 3_{10}$$

$$100_2 = (1 \times 2^2) + (0 \times 2^1) + (0 \times 2^0) = 4_{10}$$

and so on. Again, fractional values are represented with negative powers of the radix:

$$1001.101 = 2^3 + 2^0 + 2^{-1} + 2^{-3} = 9.625_{10}$$

In general, for the binary representation of $Y = \{ \dots b_2 b_1 b_0 . b_{-1} b_{-2} b_{-3} \dots \}$, the value of Y is

$$Y = \sum_i (b_i \times 2^i)$$

A.3 CONVERTING BETWEEN BINARY AND DECIMAL

It is a simple matter to convert a number from binary notation to decimal notation. In fact, we showed several examples in the previous subsection. All that is required is to multiply each binary digit by the appropriate power of 2 and add the results.

To convert from decimal to binary, the integer and fractional parts are handled separately.

Integers

For the integer part, recall that in binary notation, an integer represented by

$$b_{m-1} b_{m-2} \dots b_2 b_1 b_0 \quad b_i = 0 \text{ or } 1$$

has the value

$$(b_{m-1} \times 2^{m-1}) + (b_{m-2} \times 2^{m-2}) + \dots + (b_1 \times 2^1) + b_0$$

Suppose it is required to convert a decimal integer N into binary form. If we divide N by 2, in the decimal system, and obtain a quotient N_1 and a remainder R_0 , we may write

$$N = 2 \times N_1 + R_0 \quad R_0 = 0 \text{ or } 1$$

Next, we divide the quotient N_1 by 2. Assume that the new quotient is N_2 and the new remainder R_1 . Then

$$N_1 = 2 \times N_2 + R_1 \quad R_1 = 0 \text{ or } 1$$

so that

$$N = 2(2N_2 + R_1) + R_0 = (N_2 \times 2^2) + (R_1 \times 2^1) + R_0$$

If next

$$N_2 = 2N_3 + R_2$$
